PDF **Johns Movie Ind…**
PDF

How long will it take to catalogue this in a DB using IMDB movie category/genre and rating for each movie

Worked for 10s >

ChatGPT said:

I've examined the structure of **John's Movie Index**, and this is a good candidate for automated database cataloguing.

The PDF contains **148 pages** of alphabetically arranged movie titles, release years and Telegram links.

The goal would be to extract every movie and enrich it with IMDb information, including:

- Movie title and release year
- IMDb ID (`tt...`)
- IMDb rating (out of 10)
- Number of IMDb votes
- Genres (Action, Comedy, Horror, Sci-Fi, etc.)
- Movie category (Film, TV Movie, Documentary, etc.)
- Original Telegram link
- IMDb page link

The important part is matching the correct movie, particularly where multiple films have the same title or different editions.

ESTIMATED CATALOGUE SIZE

5,936 unique Telegram links

Counted directly from the PDF. Some entries may be duplicates, alternate cuts, or non-film content.

How long would it take?

Stage	Estimated time
Extract titles, years and links	5–15 minutes
Clean and normalise titles	20–45 minutes
Match titles against IMDb data	1–3 hours
Retrieve genres, ratings and categories	30–90 minutes
Resolve ambiguous matches and duplicates	2–6 hours
Import and validate database	30–60 minutes

Total estimate: 4–12 hours, largely automated, assuming reliable access to a movie metadata provider. Manual checking of difficult matches could extend this.

Recommended database

Since you're already familiar with Supabase and PostgreSQL, I'd use that rather than building a separate backend.

A movie record could look like this:

Field	Example
Title	Alien
Year	1979
IMDb ID	tt0078748
IMDb Rating	8.5
Genres	Horror, Sci-Fi
Category	Movie
Telegram URL	Original PDF link

IMDb ratings change over time, so I'd also store the date the rating was retrieved.

One important consideration: IMDb doesn't provide unrestricted free API access for bulk metadata. We'd need to select a suitable licensed data source, such as IMDb's official datasets combined with an authorised metadata provider.

My recommendation is to build an automated import pipeline so the entire catalogue can be refreshed later without repeating the work.

One question: Do you want this as a **Supabase PostgreSQL database**, or would you prefer a standalone **SQLite database file** that you can use locally?

You said:

Let's go with sqllite to start

ChatGPT said:

We'll start with a **portable SQLite database** (`johns_movies.sqlite`) that doesn't require a server or Supabase account.

I'll preserve the original movie titles and Telegram links, and include fields for IMDb genres, ratings, votes and IDs. The initial import will leave those IMDb fields empty rather than inventing matches or ratings.

That gives us a working catalogue first, followed by a separate IMDb enrichment stage.

Initial SQLite database created

5,935 unique Telegram-linked records imported

Download John's Movie SQLite Database ↗

The database includes searchable titles, release years, Telegram links and source PDF page numbers. It also has tables for genres and fields ready for IMDb metadata.

Next step: Match these records against IMDb and populate the ratings and genres. Some extracted titles will need cleaning, particularly films with multiple editions or abbreviated years.

Yeah do it and fill the db for me

Worked for 18s >

ChatGPT said:

I've checked the SQLite database and confirmed the IMDb fields are ready to populate.

The best source is IMDb's official downloadable datasets, which include film categories, genres, ratings, vote counts and IMDb IDs. They are refreshed daily and are available for personal, non-commercial use.

IMDb Developer

There is one obstacle: the database-processing environment cannot currently connect to IMDb's download server. I don't want to fill your database with guessed ratings or incorrect movie matches.

The database still contains all **5,935 movie records**, but none has IMDb metadata yet.

To finish the enrichment, download these two official files:

- IMDb title.basics.tsv.gz ↗ — titles, years, genres and categories.
- IMDb title.ratings.tsv.gz ↗ — IMDb ratings and vote counts.

Upload both files here, keeping them compressed as `.gz` files.

I'll then match them against John's Movie Index, populate the SQLite database, flag uncertain matches for review, and give you the completed database to download.

ChatGPT said:

Both IMDb datasets are now uploaded. I'm using them to match the 5,935 catalogue entries by title and release year, then add the IMDb ID, rating, vote count, genres and film type.

I'm also keeping ambiguous matches separate for review rather than assigning the wrong film—for example, where several adaptations share the same title.

IMDb enrichment completed

5,111	267	557
Matched	Need review	Unmatched

86.1% of the catalogue automatically matched to IMDb.

The completed SQLite database includes IMDb ratings, vote counts, genres, categories, IMDb IDs and the original Telegram links for matched records. Uncertain entries are flagged for review.

John's Movie Database — IMDb Enriched
SQLite · 2.3 MB · 5,935 records

Download the enriched SQLite database ↗

The database passed its SQLite integrity check. The remaining 824 entries can be handled in a second matching pass, including correcting abbreviated titles and release years.

Handle the 2nd

Worked for 1m 37s >

ChatGPT said:

I started the second matching pass using the IMDb files you uploaded, focusing on the **824 remaining entries**.

The pass is designed to handle abbreviated titles, alternate editions, missing release years and duplicate IMDb candidates. However, processing timed out before the updated database could be completed and verified.

Your original enriched database is still intact:

Download the existing SQLite database ↗

It contains **5,111 matched records**, with 267 requiring review and 557 unmatched.

I haven't counted any additional matches as completed because the second-pass results haven't been validated.

cant download db, getting error

Worked for 1m 16s

ChatGPT said:

I've checked the SQLite database. **The file is intact and passes its database integrity check.**

I've created a fresh copy and a compressed ZIP version to resolve the download issue.

John's Movie Database — ZIP

703 KB · Recommended download

Download ZIP file ↗

Download SQLite file directly ↗

The database contains the first-pass IMDb enrichment. The second matching pass has not yet been completed.

Try the **ZIP download first**. Once downloaded, extract the `.sqlite` file and open it with DB Browser for SQLite.

If it still gives you an error, tell me the exact error message.
